# 10 Minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook* 

Customarily, we import as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: import matplotlib.pyplot as plt
```

## **Object Creation**

See the Data Structure Intro section

Creating a series by passing a list of values, letting pandas create a default integer index:

```
In [4]: s = pd.Series([1,3,5,np.nan,6,8])
In [5]: s
Out[5]:
0    1
1    3
2    5
3    NaN
4    6
5    8
dtype: float64
```

Creating a DataFrame by passing a numpy array, with a datetime index and labeled columns:

```
1/2/2016
```

```
10 Minutes to pandas — pandas 0.17.1 documentation
```

```
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804

2013-01-04 0.721555 -0.706771 -1.039575 0.271860

2013-01-05 -0.424972 0.567020 0.276232 -1.087401

2013-01-06 -0.673690 0.113648 -1.478427 0.524988
```

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```
In [10]: df2 = pd.DataFrame({ 'A' : 1.,
                                   'B' : pd.Timestamp('20130102'),
   . . . . :
                                   'C' : pd.Series(1,index=list(range(4)),dtype='float
   . . . . :
                                   'D' : np.array([3] * 4,dtype='int32'),
   . . . . :
                                   'E' : pd.Categorical(["test","train","test","train"
   . . . . :
                                   'F' : 'foo' })
   . . . . :
   . . . . :
In [11]: df2
Out[11]:
               B C D E
                                    F
  Α
  1 2013-01-02 1 3 test foo
1 2013-01-02 1 3 train foo
0
1
2 1 2013-01-02 1 3 test foo
3 1 2013-01-02 1 3 train foo
```

Having specific dtypes

```
In [12]: df2.dtypes
Out[12]:
A         float64
B         datetime64[ns]
C         float32
D         int32
E         category
F         object
dtype: object
```

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [13]: df2.<TAB>
df2.A
                      df2.boxplot
df2.abs
                      df2.C
df2.add
                      df2.clip
df2.add_prefix
                    df2.clip_lower
df2.add_suffix
                     df2.clip_upper
df2.align
                     df2.columns
                     df2.combine
df2.all
                     df2.combineAdd
df2.any
                    df2.combine_first
df2.append
                     df2.combineMult
df2.apply
                   df2.compound df2.consolidate
df2.applymap
df2.as blocks
df2.asfreq
                      df2.convert_objects
df2.as_matrix
                     df2.copy
```

```
df2.corr
df2.astype
df2.at
                      df2.corrwith
df2.at_time
                      df2.count
df2.axes
                      df2.cov
df2.B
                      df2.cummax
df2.between time
                      df2.cummin
df2.bfill
                      df2.cumprod
df2.blocks
                      df2.cumsum
df2.bool
                      df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

### Viewing Data

See the Basics section

See the top & bottom rows of the frame

```
In [14]: df.head()
Out[14]:
                             В
                                       C
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
2013-01-02 1.212112 -0.173215 0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804
2013-01-04 0.721555 -0.706771 -1.039575 0.271860
2013-01-05 -0.424972 0.567020 0.276232 -1.087401
In [15]: df.tail(3)
Out[15]:
                            В
                                      C
2013-01-04 \quad 0.721555 \ -0.706771 \ -1.039575 \quad 0.271860
2013-01-05 -0.424972 0.567020 0.276232 -1.087401
2013-01-06 -0.673690 0.113648 -1.478427 0.524988
```

Display the index, columns, and the underlying numpy data

```
[-0.425 , 0.567 , 0.2762, -1.0874],
[-0.6737, 0.1136, -1.4784, 0.525 ]])
```

Describe shows a quick statistic summary of your data

Transposing your data

```
In [20]: df.T
Out[20]:
  2013-01-01 2013-01-02 2013-01-03 2013-01-04 2013-01-05 2013-01-06

                                             0.567020
                                                       0.113648
С
   -1.509059 0.119209 -0.494929 -1.039575
                                             0.276232 -1.478427
   -1.135632 -1.044236 1.071804
                                  0.271860
                                             -1.087401
                                                       0.524988
```

Sorting by an axis

Sorting by values

#### Selection

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, .at, .iat, .loc, .iloc and .ix.

See the indexing documentation Indexing and Selecting Data and MultiIndex / Advanced Indexing

#### Getting

Selecting a single column, which yields a series, equivalent to df.A

Selecting via [], which slices the rows.

#### Selection by Label

See more in Selection by Label

For getting a cross section using a label

```
In [26]: df.loc[dates[0]]
Out[26]:
A    0.469112
```

```
B -0.282863
C -1.509059
D -1.135632
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label

Showing label slicing, both endpoints are included

Reduction in the dimensions of the returned object

```
In [29]: df.loc['20130102',['A','B']]
Out[29]:
A     1.212112
B     -0.173215
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value

```
In [30]: df.loc[dates[0],'A']
Out[30]: 0.46911229990718628
```

For getting fast access to a scalar (equiv to the prior method)

```
In [31]: df.at[dates[0],'A']
Out[31]: 0.46911229990718628
```

#### Selection by Position

See more in Selection by Position

Select via the position of the passed integers

```
In [32]: df.iloc[3]
Out[32]:
A    0.721555
B    -0.706771
C    -1.039575
D    0.271860
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python

By lists of integer position locations, similar to the numpy/python style

For slicing rows explicitly

For slicing columns explicitly

For getting a value explicitly

```
In [37]: df.iloc[1,1]
Out[37]: -0.17321464905330858
```

For getting fast access to a scalar (equiv to the prior method)

```
In [38]: df.iat[1,1]
Out[38]: -0.17321464905330858
```

#### **Boolean Indexing**

Using a single column's values to select data.

A where operation for getting.

```
In [40]: df[df > 0]
Out[40]:
                        В
                                 C
                                          D
2013-01-01 0.469112
                      NaN
                               NaN
                                        NaN
2013-01-02 1.212112
                      NaN 0.119209
                                        NaN
2013-01-03
             NaN
                      NaN NaN 1.071804
2013-01-04 0.721555
                       NaN
                               NaN 0.271860
2013-01-05 NaN 0.567020 0.276232
                                        NaN
              NaN 0.113648
2013-01-06
                           NaN 0.524988
```

Using the isin() method for filtering:

```
In [41]: df2 = df.copy()
In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']
In [43]: df2
Out[43]:
                  Α
                            В
                                                       Е
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
2013-01-02 1.212112 -0.173215 0.119209 -1.044236
                                                     one
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804
                                                     two
2013-01-04 0.721555 -0.706771 -1.039575 0.271860 three
2013-01-05 -0.424972 0.567020 0.276232 -1.087401
                                                   four
2013-01-06 -0.673690 0.113648 -1.478427 0.524988 three
```

### Setting

Setting a new column automatically aligns the data by the indexes

Setting values by label

```
In [48]: df.at[dates[0],'A'] = 0
```

Setting values by position

```
In [49]: df.iat[0,1] = 0
```

Setting by assigning with a numpy array

```
In [50]: df.loc[:,'D'] = np.array([5] * len(df))
```

The result of the prior setting operations

```
2013-01-06 -0.673690 0.113648 -1.478427 5 5
```

A where operation with setting.

### Missing Data

pandas primarily uses the value np.nan to represent missing data. It is by default not included in computations. See the *Missing Data section* 

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

To drop any rows that have missing data.

Filling missing data

```
In [59]: df1.fillna(value=5)
```

```
Out[59]:

A B C D F E

2013-01-01 0.000000 0.000000 -1.509059 5 5 1

2013-01-02 1.212112 -0.173215 0.119209 5 1 1

2013-01-03 -0.861849 -2.104569 -0.494929 5 2 5

2013-01-04 0.721555 -0.706771 -1.039575 5 3 5
```

To get the boolean mask where values are nan

## **Operations**

See the Basic section on Binary Ops

#### Stats

Operations in general exclude missing data.

Performing a descriptive statistic

```
In [61]: df.mean()
Out[61]:
A    -0.004474
B    -0.383981
C    -0.687758
D    5.000000
F    3.000000
dtype: float64
```

Same operation on the other axis

```
In [62]: df.mean(1)
Out[62]:
2013-01-01     0.872735
2013-01-02     1.431621
2013-01-03     0.707731
2013-01-04     1.395042
2013-01-05     1.883656
2013-01-06     1.592306
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1,3,5,np.nan,6,8], index=dates).shift(2)
In [64]: s
Out[64]:
2013-01-01
           NaN
2013-01-02 NaN
2013-01-03 1
2013-01-04
              3
2013-01-05
              5
2013-01-06
           NaN
Freq: D, dtype: float64
In [65]: df.sub(s, axis='index')
Out[65]:
                           В
                                     C
                                         D
2013-01-01
                NaN
                         NaN
                                   Nan Nan Nan
          NaN
                                  NaN NaN NaN
2013-01-02
                        NaN
2013-01-03 -1.861849 -3.104569 -1.494929 4
                                            1
2013-01-04 -2.278445 -3.706771 -4.039575
                                            0
2013-01-05 -5.424972 -4.432980 -4.723768 0 -1
2013-01-06
               NaN
                        NaN
                                  NaN NaN NaN
```

#### **Apply**

Applying functions to the data

```
In [66]: df.apply(np.cumsum)
Out[66]:
                            В
                                              F
2013-01-01 0.000000 0.000000 -1.509059 5 NaN
2013-01-02 1.212112 -0.173215 -1.389850 10 1
2013-01-03 0.350263 -2.277784 -1.884779 15
                                            3
2013-01-04 1.071818 -2.984555 -2.924354 20
                                             6
2013-01-05 0.646846 -2.417535 -2.648122 25
                                            10
2013-01-06 -0.026844 -2.303886 -4.126549 30 15
In [67]: df.apply(lambda x: x.max() - x.min())
Out[67]:
    2.073961
Α
В
    2.671590
С
    1.785291
D
    0.000000
F
    4.000000
dtype: float64
```

#### Histogramming

See more at Histogramming and Discretization

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
In [69]: s
Out[69]:
0
     2
1
2
     1
3
     2

Out[70]:
4
6
     2
2
     2
1
     1
dtype: int64
```

### String Methods

Series is equipped with a set of string processing methods in the *str* attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in *str* generally uses regular expressions by default (and in some cases always uses them). See more at *Vectorized String Methods*.

```
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'ca
In [72]: s.str.lower()
Out[72]:
1
        b
2
        С
3
    aaba
4
    baca
5
     NaN
6
     caba
7
     dog
8
     cat
dtype: object
```

## Merge

#### Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section

Concatenating pandas objects together with concat():

```
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
          0
                    1
                               2
0 -0.548702 1.467327 -1.015962 -0.483075
1 1.637550 -1.217659 -0.291519 -1.745505
2 - 0.263952 \quad 0.991460 \quad -0.919069 \quad 0.266046
3 - 0.709661 \quad 1.669052 \quad 1.037882 \quad -1.705775

```

Join

SQL style merges. See the Database style joining

```
In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})
In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})
In [79]: left
Out[79]:
   key lval
0 foo    1
1 foo    2
```

```
In [80]: right
Out[80]:
  key rval
  foo
           4
  foo
           5
In [81]: pd.merge(left, right, on='key')
Out[81]:
   key
              rval
        lval
0
  foo
           1
1
  foo
                  5
           1
2
  foo
           2
                  4
  foo
```

#### **Append**

Append rows to a dataframe. See the Appending

```
In [82]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A','B','C','D'])
In [83]: df
Out[83]:
         Α
                   В
                             C
0 1.346061 1.511763 1.627081 -0.990582

4 -0.727965 -0.589346 0.339969 -0.693205
5 -0.339355 0.593616 0.884345 1.591431
6 0.141809 0.220390 0.435589 0.192451
7 -0.096701 0.803351 1.715071 -0.708758
8 1.453749 1.208843 -0.080952 -0.264610
```

## Grouping

By "group by" we are referring to a process involving one or more of the following steps

Splitting the data into groups based on some criteria

- Applying a function to each group independently
- Combining the results into a data structure

See the Grouping section

```
'C' : np.random.randn(8),
  . . . . :
                      'D' : np.random.randn(8)})
  . . . . :
In [87]: df
Out[87]:
                 C
   Α
         В
       one -1.202872 -0.055224
0 foo
1 bar
      one -1.814470 2.395985
       two 1.018601 1.552825
2 foo
3 bar three -0.595447 0.166599
       two 1.395433 0.047609
4 foo
       two -0.392670 -0.136473
5 bar
      one 0.007207 -0.561757
7 foo three 1.928123 -1.623033
```

Grouping and then applying a function sum to the resulting groups.

Grouping by multiple columns forms a hierarchical index, which we then apply the function.

## Reshaping

See the sections on Hierarchical Indexing and Reshaping.

#### Stack

```
In [90]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
                               'foo', 'foo', 'qux', 'qux'],
['one', 'two', 'one', 'two',
                                 'one', 'two', 'one', 'two']]))
   . . . . :
   . . . . :
In [91]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [92]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B']
In [93]: df2 = df[:4]
In [94]: df2
Out[94]:
first second
bar one
               0.029399 -0.542108
      two
              0.282696 -0.087302
baz
      one
              -1.575170 1.771208
      two
               0.816482 1.100230
```

The stack() method "compresses" a level in the DataFrame's columns.

```
In [95]: stacked = df2.stack()
In [96]: stacked
Out[96]:
first second
                 0.029399
bar
             Α
      one
             B -0.542108
                 0.282696
      two
             Α
             B -0.087302
baz
             A -1.575170
      one
             В
                 1.771208
      two
            A 0.816482
             B 1.100230
dtype: float64
```

With a "stacked" DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack() is unstack(), which by default unstacks the last level:

```
Out[98]:
second
             one
                        two
first
     A 0.029399 0.282696
bar
      B -0.542108 -0.087302
baz
      A -1.575170 0.816482
      B 1.771208 1.100230
In [99]: stacked.unstack(0)
Out[99]:
first
              bar
                         baz
second
      A 0.029399 -1.575170
one
      B -0.542108 1.771208
      A 0.282696 0.816482
two
      B -0.087302 1.100230
```

#### **Pivot Tables**

See the section on Pivot Tables.

```
In [100]: df = pd.DataFrame({'A' : ['one', 'one', 'two', 'three'] * 3,
                             'B' : ['A', 'B', 'C'] * 4,
                             'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2
                             'D' : np.random.randn(12),
   . . . . . :
                             'E' : np.random.randn(12)})
   . . . . . :
   . . . . . :
In [101]: df
Out[101]:
       Α
             foo 1.418757 -0.179666
0
      one
          A
              foo -1.879024 1.291836
1
      one
          В
              foo 0.536826 -0.009614
2
     two
          C
             bar 1.006160 0.392149
3
   three A
             bar -0.029716 0.264599
4
     one B
5
     one C bar -1.146178 -0.057409
     two A foo 0.100900 -1.425638
6
7
    three B foo -1.035018 1.024098
8
     one C foo 0.314665 -0.106062
9
      one A bar -0.773723 1.824375
10
      two B bar -1.170653 0.595974
11
   three C bar 0.648740 1.167115
```

We can produce pivot tables from this data very easily:

```
1/2/2016
```

```
10 Minutes to pandas — pandas 0.17.1 documentation
```

```
B NaN -1.035018
C 0.648740 NaN
two A NaN 0.100900
B -1.170653 NaN
C NaN 0.536826
```

### **Time Series**

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the *Time Series section* 

Time zone representation

```
In [106]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
In [107]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [108]: ts
Out[108]:
2012-03-06
            0.464000
2012-03-07
             0.227371
2012-03-08
            -0.496922
2012-03-09
             0.306389
2012-03-10 -2.290613
Freq: D, dtype: float64
In [109]: ts_utc = ts.tz_localize('UTC')
In [110]: ts_utc
Out[110]:
2012-03-06 00:00:00+00:00 0.464000
2012-03-07 00:00:00+00:00
                           0.227371
2012-03-08 00:00:00+00:00 -0.496922
2012-03-09 00:00:00+00:00
                           0.306389
2012-03-10 00:00:00+00:00 -2.290613
Freq: D, dtype: float64
```

Convert to another time zone

```
In [111]: ts_utc.tz_convert('US/Eastern')
Out[111]:
```

```
1/2/2016 10 Minutes to pandas — pandas — pandas 0.17.1 documentation
```

```
2012-03-05 19:00:00-05:00 0.464000

2012-03-06 19:00:00-05:00 0.227371

2012-03-07 19:00:00-05:00 -0.496922

2012-03-08 19:00:00-05:00 0.306389

2012-03-09 19:00:00-05:00 -2.290613

Freq: D, dtype: float64
```

Converting between time span representations

```
In [112]: rng = pd.date range('1/1/2012', periods=5, freq='M')
In [113]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [114]: ts
Out[114]:
2012-01-31 -1.134623
2012-02-29 -1.561819
2012-03-31 -0.260838
2012-04-30 0.281957
2012-05-31
             1.523962
Freq: M, dtype: float64
In [115]: ps = ts.to period()
In [116]: ps
Out[116]:
2012-01
         -1.134623
2012-02 -1.561819
2012-03 -0.260838
2012-04
         0.281957
2012-05
         1.523962
Freq: M, dtype: float64
In [117]: ps.to_timestamp()
Out[117]:
2012-01-01 -1.134623
2012-02-01 -1.561819
2012-03-01 -0.260838
2012-04-01 0.281957
2012-05-01
             1.523962
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [118]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [119]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [120]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [121]: ts.head()
Out[121]:
1990-03-01 09:00   -0.902937
```

```
1/2/2016
```

## Categoricals

Since version 0.15, pandas can include categorical data in a DataFrame. For full docs, see the *categorical introduction* and the *API documentation*.

```
In [122]: df = pd.DataFrame({"id":[1,2,3,4,5,6], "raw_grade":['a', 'b', 'b', 'a',
```

Convert the raw grades to a categorical data type.

Rename the categories to more meaningful names (assigning to series.cat.categories is inplace!)

```
In [125]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under series .cat return a new series per default).

```
In [126]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "mediu")
In [127]: df["grade"]
Out[127]:
0
    very good
1
          good
2
          good
3
    very good
4
    very good
     very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

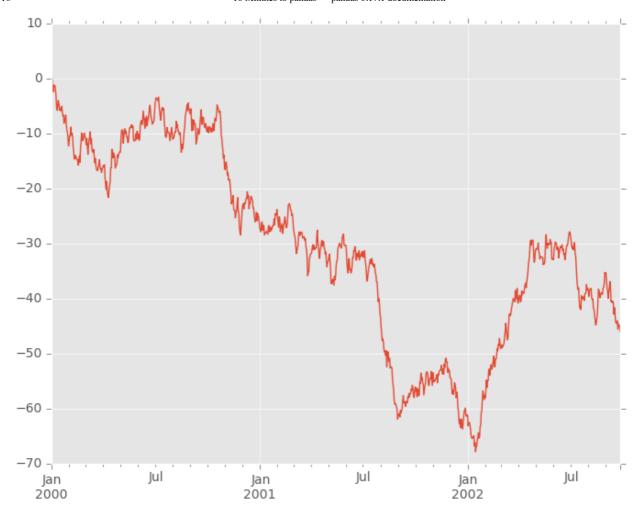

```
In [128]: df.sort_values(by="grade")
Out[128]:
  id raw_grade
                   grade
   6 e very bad
1
   2
             b
                  good
2
   3
            b
                      good
            a very good
a very good
a very good
0
   1
3
   4
4
   5
```

Grouping by a categorical column shows also empty categories.

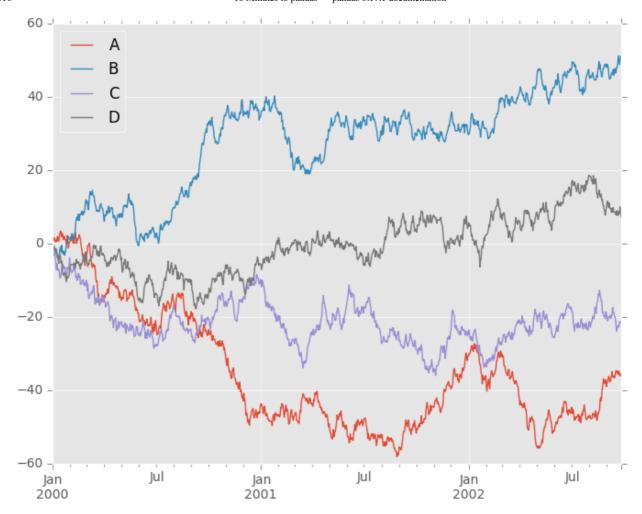

### **Plotting**

Plotting docs.

```
In [130]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', p
In [131]: ts = ts.cumsum()
In [132]: ts.plot()
Out[132]: <matplotlib.axes._subplots.AxesSubplot at 0xae3696ac>
```

On DataFrame, plot() is a convenience to plot all of the columns with labels:

## Getting Data In/Out

**CSV** 

#### Writing to a csv file

```
In [136]: df.to_csv('foo.csv')
```

#### Reading from a csv file

```
In [137]: pd.read_csv('foo.csv')
Out[137]:
     Unnamed: 0

### Gotchas

If you are trying an operation and you see an exception like:

```
>>> if pd.Series([False, True, False]):
    print("I was true")
Traceback
    ...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.a
```

See Comparisons for an explanation and what to do.

See Gotchas as well.
